Physical Models for Dynamic Simulation

Carrier Rate Equations

At the core of dynamic modeling are the carrier rate equations, which describe the temporal evolution of carrier density $N(z,t)$:

$$\frac{\partial N(z,t)}{\partial t} = \frac{J(z,t)}{qV} - \frac{N(z,t)}{\tau_N} - G(N,z,t) \cdot S(z,t)$$

]

where:

- $J(z,t)$: injection current density
- q : electronic charge
- V : active volume
- τ_N : carrier lifetime
- $G(N,z,t)$: gain coefficient dependent on carrier density
- $S(z,t)$: photon density

This differential equation captures the generation, recombination, and stimulated emission processes, forming the basis for dynamic behavior analysis.

Optical Propagation Equations

The evolution of the optical field $\psi(E(z,t))$ or photon density $\psi(S(z,t))$ along the propagation axis is modeled via the coupled wave equations, often simplified to the traveling-wave equations:

$$\frac{\partial S(z,t)}{\partial z} + \frac{1}{v_g} \frac{\partial S(z,t)}{\partial t} = \Gamma \cdot G(N,z,t) - \alpha S(z,t)$$

where:

- v_g : group velocity
- Γ : optical confinement factor
- α : internal losses

These equations are coupled with the carrier rate equations and require numerical methods for solutions.

Nonlinear and Additional Effects

In high-speed and high-power regimes, additional effects must be considered:

- Spectral dependence of gain and refractive index
